OS Project1 – Processing Scheduling

Tony Liu B05202068

April 29, 2020

1 Program

1.1 Process Scheduler

`main.c`

- Read input(scheduling policy, process info)
- Qucik Sort by process's ready_time

`scheduler_xxx.c`

- There are four policies for processes to run
  FIFO
  RR
  SJF
  PSJF
- Call `procecc_control.c` to control processing
  `fork()` the process we want to run
  control the priority of each process to use CPU

`process_control.c`

- provide tools that are used in `scheduler_xxx.c`
- `TIME_UNIT()`: the function to determine the time unit by running 10^6 times in a while loop
- `assign_core()`: call system call `sched_setaffinity()` to make process run under a particular core
- `proc_create()` : create process and write a self-defined dmesg
- `proc_kickout()`: stop the process by lowering its priority
- `proc_resume()`: resume the process by increasing its priority

1.2 Kernel Version

- Linux version 4.14.25
- `sys_printstring()` write a string with process info into the system log

Note: The way I add the system call in the kernel is the same as HW1.

2 Theoretical and Actual Results

- Test Machine: `Intel core i7 8th gen`
- Time unit: 0.001554701 sec

→ `pid` finish at `converted time unit` unit

Note: Whenever the ready time for the first process in nonzezro, we should shift the time units by their `ready_time`

3 Analysis of Results

After running the program in the four different policies, the actual results mainly match the theoretical results, with the error lying in between $5\% - 15\%$.

- Working Load: There might be other programs running while executing the programs of the project. Using `sched_scheduler()` to control the ordering cannot ensure that our programs can be run with top priority. Even if we set the priority in `SCHED_FIFO` to the highest, there is no guarantee that the programs can share CPU with other system programs. Furthermore, how CPU loads instantaneously will also affect the finish time for the programs.
- The Variation of Time Unit: CPU has the ability to change clock rate, which can be adjusted to enhance the performance of CPU when there is heavily loading. If our CPU has such function, then the time unit we use may vary from time to time, leading to errors.
- The Synchronization between Parent Process and Children Process The scheduler programs and their children processes need to communicate by some ways, and the time difference when they communicate can cause error. For example, in the program, parents use `PIPE` to make children run, and use `waitpid()` to take over the finish of children. The communication info between sender and receiver

can cause time difference, leading to the error.
On top of that, child and parent process run under different core, while they use the same way to compute the time unit. Hence, if the cores for these two process have different work loading, these two processes may be asynchronized. Suppose the core for the child has light loading and finishes earlier than parent, the parent will call `waitpid()` at a later time. In this case, when the next child is going to run, it will be delayed due to the postponement of parent, leading to error in time.
